A PROOF THAT THE MAXIMAL RANK FOR PLANE QUARTICS IS SEVEN

ALESSANDRO DE PARIS

Abstract. At the time of writing, the general problem of finding the maximal Waring rank for homogeneous polynomials of fixed degree and number of variables (or, equivalently, the maximal symmetric rank for symmetric tensors of fixed order and in fixed dimension) is still unsolved. To our knowledge, the answer for ternary quartics is not widely known and can only be found among the results of a master’s thesis by Johannes Kleppe at the University of Oslo (1999). In the present work we give a (direct) proof that the maximal rank for plane quartics is seven, following the elementary geometric idea of splitting power sum decompositions along three suitable lines.

Keywords: Waring rank, tensor rank, secant varieties.

1. Introduction

The (Waring) rank of a homogeneous polynomial is the minimum number of summands needed to express it as a sum of powers of linear forms. According to [5], the problem of finding the maximal rank for polynomials of fixed degree \(d\) and number \(n\) of variables may be called little Waring problem for polynomials, in analogy with the classical problem in number theory. The big Waring problem is a ‘generic version’, with a solution that was given by a now classical theorem of Alexander and Hirschowitz (see, e.g., [8, Theorem 3.2.2.4]). To our knowledge, contrary to the number theoretic situation, the little Waring problem for polynomials is solved only for a few values of \(n, d\).

Beyond the interest due to its connection with the classical Waring problem, this topic deserves attention as a part of tensor theory. Questions about tensors are attracting researchers because of the recent discovery of new applications (see [8]). In that respect, the focus is mainly on low-rank and general (not necessarily symmetric) tensors. Nevertheless, high-rank symmetric tensors may well provide some useful insights in a field that, in spite of its long history and great recent efforts devoted to it, seems far from being completed.

In the relatively recent book [8] (see the preamble to Chap. 9), possible ranks and border ranks are reported to be known only when \(n = 2\) or \(d = 2\) or \(n = d = 3\). A thorough study of the case \(n = 3, d = 4\) is one of the main subjects of [8]. Note that Theorem 44 of that paper would have probably been easily completed with the description of \(\sigma_6(X_{2,4}) \setminus \sigma_5(X_{2,4})\) if the fact that the maximal rank for plane quartic is seven had been known. For these reasons, the author wondered about that maximal rank. During the investigation, Kleppe’s thesis [7] was brought to our attention by Edoardo Ballico. We admit not having thoroughly checked that thesis, but we have good reasons to say that its results are highly reliable. In particular,
the maximal rank for plane quartics is seven. However, we also have good reasons to believe that the approach we follow in the present paper significantly differs and is worthy of consideration. Some of Kleppe’s results are also involved in the proof of a general bound for the rank of polynomials that is presented in [6] (see also [1], [2]). Note that the formula in that work gives a bound of nine for plane quartics. Hence, in view of the search for better general bounds and therefore in view of the little Waring problem for polynomials, a deeper understanding of the case of plane quartics may be useful.

Our basic idea is to look for summands that are forms in a lesser number of variables. In order to provide more details, let us first fix some standing conventions. An algebraically closed field $K$ of zero characteristic is fixed throughout the paper. The symmetric algebra of a $K$-vector space $V$ will be denoted by $S^* V$, with degree $d$-components denoted by $S^d V$ and with the convention that they vanish for $d < 0$. We also assume $S^1 V = V$. We keep fixed the notation $S^* , S_*$ for two such symmetric algebras on which a perfect pairing $a_1 : S^1 \times S_1 \to K$ of $K$-vector spaces is tacitly assigned (of course, $S^d$ and $S_d$ are the degree $d$ homogeneous components of $S^*$, $S_*$, respectively). The perfect pairing induces the apolarity (perfect) pairing

$$a_d : S^d \times S_d \to K$$

in each fixed degree $d$, in a natural way. Namely, it is uniquely determined by the condition

$$a_d \left( x^1 \ldots x^d, x_1 \ldots x_d \right) := \text{perm} \left( \begin{array}{ccc} a_1 \left( x^1, x_1 \right) & \ldots & a_1 \left( x^1, x_d \right) \\ \vdots & \ddots & \vdots \\ a_1 \left( x^d, x_1 \right) & \ldots & a_1 \left( x^d, x_d \right) \end{array} \right),$$

for all $x^1 \ldots x^d \in S^1$, $x_1 \ldots x_d \in S_1$, where perm denotes the permanent (a ‘signless determinant’: $\text{perm} \left( x^1_j \right) := \sum_\sigma x_1^{x_1(\sigma)}$, with $\sigma$ ranging over all permutations of the indices).

Given $s \in S^\delta$, $x \in S_d$, there exists a unique $y \in S_{d-\delta}$ such that

$$a_{d-\delta} (t, y) = a_d (st, x), \quad \forall t \in S^{d-\delta},$$

because $a_{d-\delta}$ is a perfect pairing. We call the element $y$ the contraction of $x$ by $s$ (it vanishes when $\delta > d$), and the definition extends by additivity for all $s \in S^*, x \in S_*$. We allow ourselves to borrow from the context of exterior algebras the notation for contraction:

$$y =: s \cdot x.$$

It is convenient to keep in mind two (well-known) basic rules for contractions:

$$st \cdot x = s \cdot (t \cdot x)$$

and

$$(1) \quad s \cdot xy = (s \cdot x)y + x(s \cdot y).$$

From these rules we recover a very common description of the rings $S^*$, $S_*$: they are usual polynomial rings, $S^*$ is usually denoted by $T = k \left[ y_1, \ldots, y_n \right]$, and its elements act as (constant coefficients) differential operators on the polynomials of $S_* = S = k \left[ x_1, \ldots, x_n \right]$. Our alternative notation aims at suggesting a geometric viewpoint from which (homogeneous) elements of $S_*$ are ‘contravariant’ and give
‘multipoints’ in a projective space \( \mathbb{P} \), meanwhile that of \( S^* \) are ‘covariant’ and give hypersurfaces in \( \mathbb{P} \) (nevertheless, at a technical level, the roles of the two rings are perfectly symmetric). Still in view of our more elementary geometric viewpoint, we shall use the orthogonality sign \( \perp \) with reference to the original pairing \( S^1 \times S_1 \to K \) only (and not for the apolar ideal). Therefore, \( \{x, y\}^t \), with \( x, y \in S_1 \), will denote the set of \( l \in S^1 \) that vanish at \( x, y \) (when viewed as linear forms, that is, \( l - x = l - y = 0 \)). For instance, in [7] our \( \{x, y\}^t \) would be denoted by \( (x, y)^1_1 \) (the first homogeneous component of the apolar ideal of \( (x, y) \in S \)).

We shall not use angle parentheses to denote the apolarity pairings, because we are more comfortable with using them to indicate the linear span of a set of vectors. We prefer to (formally) look at points in the projective space \( \mathbb{P}(S_1) \) as one-dimensional subspaces \( \{x\} \subseteq S_1, x \neq 0 \). When a scheme structure is needed, \( \mathbb{P}(S_1) \) may be (naturally) replaced by \( \text{Proj } S^* \) (and \( \{x\} \) by the ideal generated by \( \{x\}^t \)).

Finally, we shall sometimes make use of the partial polarization map \( f_{\delta,d}: S^\delta \to S_d \) of \( f \in S_{d+\delta} \) (cf., e.g., [8, 2.6.6]). It is simply defined by
\[
f_{\delta,d}(t) := t - f
\]
and we shall keep the notation \( f_{\delta,d} \).

Now that our standing notation is set up, let us quickly describe the idea to bound the rank we are following. In the case of a ternary quartic \( f \in S_4 \) (dim \( S_1 = 3 \)) this is easy. Indeed, let us consider in \( \mathbb{P}S^3 \) the closed subvariety \( X \) consisting of cubics that are broken in three lines:
\[
X := \{ \{x^0, x^1, x^2\} : x^0, x^1, x^2 \in S^1 \setminus \{0\} \}.
\]
Consider also the subspace
\[
Y := \{ \{c\} : c \in S^3 \setminus \{0\}, c - f = 0 \}.
\]
We have \( \dim \mathbb{P}S^3 = 9 \), \( \dim X = 6 \), \( \dim Y \geq 6 \), so that \( \dim (X \cap Y) \geq 3 \). Hence we can always find \( x^0, x^1, x^2 \in S^1 \setminus \{0\} \) such that \( x^0 x^1 x^2 - f = 0 \). We expect that, generically, \( x^0, x^1, x^2 \) should be linearly independent, and in this case we can write
\[
f = f_0(x_1, x_2) + f_1(x_0, x_2) + f_2(x_0, x_1),
\]
with \( x_0, x_1, x_2 \) being the basis of \( S_1 \) dual to \( \{x^0, x^1, x^2\} \). Moreover, we have three degrees of freedom in the decomposition, due to the possibility of moving \( x_0^4, x_1^4, x_2^4 \) among \( f_0, f_1, f_2 \) (generically, one might exploit this to reach \( \text{rk } f_i \leq 2 \)). We shall explain how to manage special cases later. The implementation of this idea will lead us to amusing exercises about very elementary objects, such as quadric cones in a three-dimensional space and the rational normal quartic curve. By solving them, in our opinion we gain a perspective from which the intricacies of high rank symmetric tensors can be usefully organized.

2. Preparation

Since we are building our main proof on the basis of quite elementary facts, even the moderately experienced reader will likely prefer to prove these facts as an exercise, instead of being bored by reading detailed proofs. That is why in this preliminary section we shall limit ourselves to the statements and a few hints.

First of all, let us recall that the rank stratification for binary forms, i.e., when \( \dim S_1 = 2 \), is well known (form a geometric viewpoint, it is based on properties of
rational normal curves). Recent references are, among many others, [8, 9.2.2], [3], as well as [7, chap. 1]. To begin with, we recall that for a binary quartic $f \in S_4$, $\text{rk} f \leq 4$. Moreover, the secant variety $X$ to the rational normal quartic curve $Q$ that consists of all $\{x^4\}$ with $x \in S_1$, is a hypersurface in $\mathbb{P}S_4$. Its complement is exactly the set of all $\{f\}$ with $\text{rk} f = 3$. The equation for $X$ is given by the condition $\det f_{2,2} = 0$, and therefore $\deg X = 3$. Points $\{f\}$ of the tangent variety, but that lies outside $Q$, are exactly those for which $\text{rk} f = 4$; the tangent to $\{x^4\} \subset Q$ is $\mathbb{P}\langle x^4, x^3y \rangle$ with $y \in S^1 - \{x\}$. We need now to describe the rank stratification of particular planes in $\mathbb{P}S_4$.

**Lemma 2.1.** Let $\dim S_1 = 2$, $S_1 = \{x_0, x_1\}$, and $W$ be a subspace of $S_4$ with $\dim W = 3$ and containing $L := \{x_0^4, x_1^4\}$. Set $A := \mathbb{P}W - \mathbb{P}L$, which can be regarded as an affine plane with line at infinity $\mathbb{F}L$, and

$$R := \{(f) \in A : \text{rk} f \neq 3\}, \quad R' := \{(f) \in A : \text{rk} f = 4\}.$$  

Then we have one of the following alternatives [7a] [7b] [2]:

1. $R'$ consists of at most two points and
   1a. $R \neq \emptyset$ is an affine conic with points at infinity exactly $\{x_0^4\}, \{x_1^4\}$, and when $R$ possesses a singular point $\{x\}$ we have $\text{rk} x = 1$ and $R' = \emptyset$; or
   1b. $R \neq \emptyset$ is an affine line with point at infinity different from $\{x_0^4\}, \{x_1^4\}$;

2. $R = R' \neq \emptyset$ is an affine line with point at infinity either $\{x_0^4\}$ or $\{x_1^4\}$, and, more precisely, $R = R' = A \cap \mathbb{P}\langle x_0^4, x_0^3x_1, x_0^2x_1^3, x_1^4 \rangle$ in the first case, $R = R' = A \cap \mathbb{P}\langle x_0x_1^3, x_1^4 \rangle$ in the other.

The proof can safely be left to the reader, but we suggest to first keep in mind that points $\{f\} \in \mathbb{P}W$ with $\text{rk} f \neq 3$ constitute a reducible cubic curve with $\mathbb{P}L$ as a component. The following geometric considerations might also be helpful. Let us look at the projection

$$\mathbb{P}S_4 - \mathbb{P}L \to \mathbb{P}(S_4/L), \quad (x) \mapsto \{x + L\},$$

so that $\mathbb{P}W$ projects onto a point $P \in \mathbb{P}(S_4/L)$. Lines $\ell$ through $P$ in $\mathbb{P}(S_4/L)$ comes from hyperplanes of $\mathbb{P}S_4$ containing $\mathbb{P}W$. Such a hyperplane meets the rational normal quartic $Q$ (consisting of all $\{x^4\}$, $x \in S_1$) in $\{x_0^4\}, \{x_1^4\}$, and further points $\{x_2^4\}, \{x_3^4\}$. If $\ell \ni P$ is not tangent (somewhere) to the projection $C$ of $Q$ (which is a conic), we have a secant line $\ell' := \mathbb{P}\langle x_3^4, x_4^4 \rangle$ that must intersect the plane $\mathbb{P}W$, and of course if $\{x\} \in \ell' \cap \mathbb{P}W$ then $\text{rk} x \leq 2$. Tangents give rank four (or rank one) forms instead. Conversely, any $\{x\} \in A$ that lies on a secant or tangent line $\ell'$ to $Q$ that does not contain $\{x_0^4\}$ or $\{x_1^4\}$, must come in the previous way from the hyperplane joining $\ell'$ and $\mathbb{P}W$. With the above said in mind, let $P_0, P_1 \in C$ be the projections of (the tangents to $Q$ at) $\{x_0^4\}, \{x_1^4\} \subset Q$, and $\ell_0$ be the line through them. Then Case [2] occurs when $P$ comes to coincide with $P_0$ or $P_1$, and Case [15] occurs when $P \in \ell_0 - \{P_0, P_1\}$. Case [14] occurs when $P \notin \ell_0$, with $R$ being singular exactly when $P = \{x\}$ also lies on $C$.

For ease of exposition, in this paper we make use of the following ad hoc terminology, related to the situation of the above lemma.
Definition 2.2. Let $W$ be a $K$-vector space, $\dim W = 3$, $y, z \in W$ distinct vectors and $R, R' \in PW - P\langle y, z \rangle$. Throughout this paper we say that $(W, y, z, R, R')$ is an $R$-configuration of type $1a$, $1b$ or $2$, if it fulfills the corresponding condition in Lemma 2.1 with $y, z$ in place of $x_0^4, x_1^4$ (without reference to $x$ in Case $1a$ nor to the polynomial description of $R = R'$ in Case $2$).

Proposition 2.3. Let $C_i = (W_i, y_i, z_i, R_i, R'_i)$, $i \in \{0, 1, 2\}$, be $R$-configurations. Let $W$ be a $K$-vector space, $\dim W = 4$, $w_0, w_1, w_2 \in W$ linearly independent vectors, and $\alpha_i : W \to W_i$, $i \in \{0, 1, 2\}$, surjective linear maps such that for each $i$, $\alpha_i$ sends $w_i$ into $0$ and the other two vectors into $y_i, z_i$ (in whatever order, but one-to-one). Finally, for each $i$, let us consider the (affine) map

$$\bar{\alpha}_i : PW - P\langle w_0, w_1, w_2 \rangle \to PW_i - P\langle x_i, y_i \rangle, \quad (w) \mapsto (\alpha_i(w))$$

and set

$$\bar{R}_i := \bar{\alpha}_i^{-1}(R_i), \quad \bar{R}'_i := \bar{\alpha}_i^{-1}(R'_i).$$

If $C_0$ and $C_1$ are not of type $2$ and

$$(2) \quad (\bar{R}_0 \cap \bar{R}_1) - (\bar{R}'_0 \cup \bar{R}'_1 \cup \bar{R}'_2) = \emptyset,$$

then the $R$-configuration $C_2$ is of type $2$, one of the others, say $C_j$, is of type $1a$ with $R_j$ a reducible conic, and $\bar{R}'_2$ is a component (plane) of $\bar{R}'_j$.

Let us outline a way to organize a proof that to some extent avoids a cumbersome analysis. The dimension of each irreducible component of the intersection $X := \bar{R}_0 \cap \bar{R}_1$ is at least one. Considering $P\langle w_0, w_1, w_2 \rangle$ as the plane at infinity, it is easy to see that there must exist a component $Y$ of $X$ with a point $P$ at infinity that does not lie in the line $P\langle w_0, w_1 \rangle$. Note that $\bar{R}'_0$ is a (possibly empty) union of lines through $\langle w_0 \rangle$, and $\bar{R}'_1$ a union of lines through $\langle w_1 \rangle$. If $C_2$ is not of type $2$, then the condition (2) above would imply that $P = \langle w_2 \rangle$ and that $Y$ is a line. But this is possible only when $C_0, C_1$ are of type $1$, with $R_0, R_1$ reducible conics. But recall that if $R_i$ is reducible, then $R'_i$ is empty, and note that when $R_0, R_1$ are reducible, the intersection $X$ must also contain two lines with points at infinity $\langle w_0 \rangle, \langle w_1 \rangle$. Since that picture is incompatible with condition (2), we have that $C_2$ must be of type $2$ and that $\bar{R}'_2$ must be a plane containing $Y$.

Now, the line at infinity of $\bar{R}'_2$ is either $P\langle w_0, w_2 \rangle$ or $P\langle w_1, w_2 \rangle$, and let it be $P\langle w_j, w_2 \rangle$ with the appropriate $j \in \{0, 1\}$. If $\bar{R}'_2 \cap \bar{R}_j \neq \emptyset$, then this intersection is a union of lines through $\langle w_j \rangle$; hence it can not contain $Y$ and (2) would fail. Therefore, $\bar{R}'_2 \subseteq \bar{R}_j$ and henceforth $\bar{R}'_j$ is reducible. This immediately implies that also $R_j$ is reducible and that $C_j$ is of type $1a$.

Let us now state what happens when the situation of Lemma 2.1 degenerates ‘by collision’ of $\langle x_0^4 \rangle$ and $\langle x_1^4 \rangle$.

Lemma 2.4. Let $\dim S_1 = 2$, $S_1 = \langle x_0, x_1 \rangle$, and $W$ be a subspace of $S_4$ with $\dim W = 3$ and containing $L := \langle x_0^4, x_0^3x_1 \rangle$. Set $A := PW - PL$, which can be regarded as an affine plane with line at infinity $PL$, and

$$R := \{(f) \in A : \text{rk} f \neq 3\}, \quad R' := \{(f) \in A : \text{rk} f = 4\}.$$

Then $R'$ consists of at most two points, and we have one of the following alternatives $[1a]$ $[1b]$ $[2]$. 

Proof. Let $\sigma : x^0, x^1 \in S^1$ such that $x^0 x^1 \neq f = 0$. Then $\text{rk} f \leq 7$.

Proposition 2.5. Let $\dim S_1 = 3, f \in S_1$. If there exist linearly independent $x^0, x^1 \in S^1$ such that $x^0 x^1 \neq f = 0$, then $\text{rk} f \leq 7$.

Proof. Let us choose $x_2 \in \{x^0, x^1\} - \{0\}, x_1 \in \{x^0\} - \{x_2\}, x_0 \in \{x^1\} - \{x_2\}$, and set

$$V_0 := S^4 \langle x_1, x_2 \rangle, \quad V_1 := S^4 \langle x_0, x_2 \rangle.$$

From $x^0 x^1 \neq f = 0$ readily follows that $f \in V_0 + V_1$, that is, $f = f_0 + f_1$ with $f_0 \in V_0, f_1 \in V_1$. Hence $\text{rk} f = \text{rk} (f_0 + f_1) \leq \text{rk} f_0 + \text{rk} f_1 \leq 8$, because $f_0, f_1$ are polynomials in two variables. Note that, moreover, $f = (f_0 + k x_2^4) + f_1 - k x_2^4$ for all $k \in K$. Then $\text{rk} f = 8$ only if $\text{rk} (f_0 + k x_2^4) = \text{rk} (f_1 - k x_2^4) = 4$ for all $k \in K$.

Let us set

$$W_0 := \{f_0, x_0 x_1^4, x_2^4\}, \quad W_1 := \{x_0^4, f_1, x_2^4\}.$$

If $\dim W_0 = 2$ or $\dim W_1 = 2$, then $\text{rk} f_0 \leq 2$ or $\text{rk} f_1 \leq 2$. Hence we can assume that $\dim W_0 = \dim W_1 = 3$, so that Lemma 2.1 applies to both $W_0$ and $W_1$. According to the lemma,

$$\text{rk} (f_0 + k x_2^4) = \text{rk} (f_1 - k x_2^4) = 4 \quad \forall k \in K$$

can happen only in Case 2 and, more specifically, only when $f_0 \in \{x_1 x_2^3, x_2^4\}, f_1 \in \{x_0 x_2^3, x_2^4\}$. But in this case we have $f = f_0 + f_1 \in \{x_1 x_2^3, x_2^4\}$, with $x \in \{x_0, x_1\}$, so that $f$ is a polynomial in two variables $x, x_2$ (actually, of rank four).  

3. THE GENERAL CASE

Proposition 3.1. Let $\dim S_1 = 3, f \in S_4$. If there exist linearly independent $x^0, x^1, x^2 \in S^1$ such that $x^0 x^1 x^2 \neq f = 0$ then $\text{rk} f \leq 7$.

Proof. Let $(x_0, x_1, x_2)$ be the basis of $S_1$ dual to $(x^0, x^1, x^2)$ and set

$$V_0 := S^4 \langle x_1, x_2 \rangle, \quad V_1 := S^4 \langle x_0, x_2 \rangle, \quad V_2 := S^4 \langle x_0, x_1 \rangle$$

($V_0, V_1, V_2 \subset S_4$). Let

$$\sigma : V_0 \oplus V_1 \oplus V_2 \rightarrow V_0 + V_1 + V_2$$

be the canonical map $(v_0, v_1, v_2) \mapsto v_0 + v_1 + v_2$. We have

$$\text{Ker} \sigma = \{w_0, w_1, w_2\},$$
with
\[ w_0 := (0, x_0^4, -x_0^4), \quad w_1 := (x_1^4, 0, -x_1^4), \quad w_2 := (x_2^4, -x_2^4, 0). \]

From \( x^0 x^1 x^2 - s = 0 \) readily follows that \( f \in V_0 + V_1 + V_2 \). Then \( W := \sigma^{-1}(\{ f \}) \) is a four-dimensional vector space. For each \( i \in \{0, 1, 2\} \), let \( W_i \) be the image of \( W \) in the summand \( V_i \) through the projection map \( V_0 \oplus V_1 \oplus V_2 \to V_i \), and let us denote by \( \alpha_i \) the restriction \( W \to W_i \). For all \( w \in \sigma^{-1}(f) \) we have
\[ f = f_0 + f_1 + f_2, \quad f_i := \alpha_i(w) \in W_i \ \forall i. \]

From (3) it follows that
\[ x_1^4, x_2^4 \in W_0, \quad x_0^4, x_2^4 \in W_1, \quad x_1^4, x_2^4 \in W_2, \]

hence for every decomposition (4) we have
\[ W_0 = \{ f_0, x_1^4, x_2^4 \}, \quad W_1 = \{ x_0^4, f_1, x_2^4 \}, \quad W_2 = \{ x_0^4, x_1^4, f_2 \} \]

therefore \( 2 \leq \dim W_i \leq 3 \) for each \( i \).

If \( \dim W_i = 2 \) for some \( i \), say \( i = 0 \), then it must be \( W_0 = (x_1^4, x_2^4) \), and we can choose a suitable \( w \in \sigma^{-1}(f) \) that gives a decomposition (4) with \( f_0 = 0 \). This immediately implies that \( x^1 x^2 - f = 0 \), and the statement follows from Proposition 2.3. Thus, from now on, we can assume that \( \dim W_0 = \dim W_1 = \dim W_2 = 3 \).

According to Lemma 2.1, we get three R-configurations \( C_i = (W_i, y_i, z_i, R_i, R'_i), \) \( i \in \{0, 1, 2\} \), with the obvious meaning of the notation. Note that we can use Proposition 2.3 and borrow the notation \( \overline{R}_i, \overline{R}'_i \) from there. Suppose that there exists \( P \in (\overline{R}_0 \cap \overline{R}_1) - (\overline{R}'_0 \cup \overline{R}'_1 \cup \overline{R}'_2) \). We can certainly find a representative vector \( w \) of \( P \) (i.e., a generator) such that \( \sigma(w) = f \). Hence we get a decomposition (4) with \( \rk f_0 \leq 2, \rk f_1 \leq 2, \rk f_2 \leq 3 \), which immediately implies that \( \rk f \leq 7 \). Thus the statement is proved whenever condition (2) in Proposition 2.3 fails for \( C_0, C_1, C_2 \). According to the proposition, \( \rk f \leq 7 \) is still to be proven only in the following two occurrences:

(I) up to possibly reordering the indices, \( W_2 = \{ x_0^4, x_0 x_1^3, x_1^4 \} \), \( R_1 \) is a reducible conic, and the plane \( \overline{R}'_2 \) is a component of \( \overline{R}'_1 \) (4); or

(II) at least two among \( C_0, C_1, C_2 \) are of type 2.

The workaround shall use in these cases is basically a change of variables. Let \( x'_0, x'_1, x'_2 \in S_1 \) be linearly independent and let \( (x'^0, x'^1, x'^2) \) be the basis of \( S^1 \) dual to \( (x_0, x_1, x_2) \). In each case, we shall choose \( x'_0, x'_1, x'_2 \) in such a way that the decomposition (4) gives, after a linear substitution, again a decomposition of the form
\[ f = f'_0 + f'_1 + f'_2, \quad f'_0 \in S^1 \langle x'_1, x'_2 \rangle, \quad f'_1 \in S^1 \langle x'_0, x'_2 \rangle, \quad f'_2 \in S^1 \langle x'_0, x'_1 \rangle. \]

This is equivalent to say that the choice of the new variables again gives \( x'^0 x'^1 x'^2 - f = 0 \). Hence we can define new spaces \( W', W'_0, W'_1, W'_2 \), and apply the previous

\[ 1 \text{We can exclude that } W_2 = \{ x_0^4, x_0 x_1^3, x_1^4 \} \text{ because in this case } R'_2 = P \langle x_0^4, x_0 x_1^3, x_1^4 \rangle. \]
analysis. In particular, for each $i$, $f_i' \in W_i$ and
\begin{equation}
W'_0 = \left\{ f_0', x_1^4, x_2^4 \right\}, \quad W'_1 = \left\{ x_0^4, f_1', x_2^4 \right\}, \quad W'_2 = \left\{ x_0^4, x_1^4, f_2' \right\}.
\end{equation}

Let us now face Case II. Since $C_1$ is of type 1a with $R_1$ containing a singular point \((x)\), according to Lemma 2.4.1a we have \(\text{rk} \ x = 1\). We can choose a \(w = (f_1, f_2, f_3)\) that gives a decomposition \((1)\) with \(f_1 \in (x)\). Hence \(f_1 = (\alpha x_0 + \beta x_2)^4\) with \(\alpha, \beta \neq 0\). Since \(\{f_1\} = (x)\) is contained in both components of \(R_1\), we have that \(w \in R^2\), hence \((f_2) \in R_2 = \mathbb{P}\{x_0 x_1^3, x_1^4\} - \{x_1^4\}\). Up to adding to \(w\) a suitable multiple of \(w_0\), we can assume that \(f_2 = \gamma x_0 x_1^3\), with \(\gamma \neq 0\) (basically, we are moving the monomial in \(x_1^4\) of \(f_2\) into \(f_0\)). By rescaling \(x_0, x_1, x_2\) we can further simplify:
\[f_1 = (x_0 + x_2)^4, \quad f_2 = x_0 x_1^3.\]

Now let us set \(x'_0 := x_0 + x_2, x'_1 := x_1, x'_2 := x_2\). By substitution we get
\[f = f_0' + x'_0^4 + x'_0 x'_1^3,
\]
with \(f_0' \in S^3 (x'_1, x'_2)\), which can be viewed as a decomposition of the form \((\mathbb{I})\) with \(f'_0 = 0\). Hence \(\dim W'_1 = 2\), and we already know that \(\text{rk} \ f \leq 7\) in such a case.

We are left with Case III. We can assume that (up to possibly reordering the indices) the R-configurations \(C_0\) and \(C_1\) are of type 2. We have to consider the following subcases:
\begin{enumerate}[label=(\roman*)]
\item \(W_0 = \{x_1^4, x_1^3 x_2, x_2^4\}, W_1 = \{x_0^4, x_0^3 x_2, x_2^4\}\);
\item \(W_0 = \{x_1^4, x_1^3 x_2, x_2^4\}, W_1 = \{x_0^4, x_0 x_2^3, x_2^4\}\), or \(W_0 = \{x_1^4, x_1 x_2^3, x_2^4\}\);
\item \(W_0 = \{x_1^4, x_1 x_2^3, x_2^4\}, W_1 = \{x_0^4, x_0 x_2^3, x_2^4\}\).
\end{enumerate}

We preliminary also assume that \(C_2\) is not of type 2 (the opposite case will be discussed at the end).

In Case III if \(x_2^4 - f \neq 0\) (that is, the monomial \(x_2^4\) occurs with a nonzero coefficient in \(f\), considered as a polynomial in \(x_0, x_1, x_2\)), let us set \(x'_0 := x_0, x'_1 := x_1, x'_2 := k x_0 + x_2\). Taking into account (5), we readily get from (4) a decomposition in the form (3). Taking into account (7), we also can fix \(k\) in such a way that neither \(W'_1\) nor \(W'_2\) gives a R-configuration of type 2 (recall we are also assuming that \(C_2\) is not of type 2). Hence in the new variables we fall outside Case III so that \(\text{rk} \ f \leq 7\) has already been proved.

Still considering Case III but now with \(x_2^4 - f = 0\), the appropriate substitution is of the form \(x'_0 := x_0, x'_1 := x_1, x'_2 := h x_0 + k x_1 + x_2\). The key point here is that we can choose \(h, k\) and further scalars \(\alpha, \beta\) in such a way that \(g'_2 := f'_2 + \alpha x_0^4 + \beta x_1^4\) is a 4-th power of a linear form (details are not difficult and left to the reader), hence its rank is at most one. Moreover, for a generic choice of \(\gamma \in K\), the rank of both polynomials \(g'_0 := f'_0 - \alpha x_1^4 + \gamma x_2^4\) and \(g'_1 := f'_1 - \beta x_0^4 - \gamma x_2^4\) is at most three. Hence the rank of \(f = g'_0 + g'_1 + g'_2\) is at most \(3 + 3 + 1 = 7\), as required.

In Case III up to possibly exchanging the indices 0, 1, we can assume that \(W_0 = \{x_1^4, x_1 x_2^3, x_2^4\}\) and \(W_1 = \{x_0^4, x_0 x_2^3, x_2^4\}\). Here we can proceed exactly as in the subcase III when \(x_2^4 - f \neq 0\) (without any need of this restrictive assumption, because of the presence of \(x_0 x_2^3\) in \(f_1\)).

\footnote{As a cross-check, note that the dual basis is \(x_0^0, x_1^1, x_2^2 = -x_0^0 + x_2^2\), and indeed \(x_0 x_1^4, x_2^2 - f = 0\) (in the present case \(x_0^0 x_1^4 - f = 0\) because \(f_2 = x_0 x_1^3\)).}
In Case III it suffices to set \( x'_0 = x_0 + kx_1, \ x'_1 = x_1, \ x'_2 = x_2 \) and choose \( k \) in such a way that \( \dim W_0^2 = 2 \) (which gives an already settled case).

Note that Case III is now solved whenever we have exactly two R-configurations of type 2. The only event left is when all R-configurations are of type 2. With \( k \) not of type 2 only in Case II, i with such a way that \( \dim W_0^2 \leq \dim Y \).

It follows, in particular, that \( \dim W_0^2 \geq 2 \) (which gives an already settled case).

4. On reduction to the general case

At the end of the Introduction, we explained how to find triples \( x^0, x^1, x^2 \in S^1 \) such that \( x^0 x^1 x^2 = f = 0 \) (dim \( S_1 = 3, f \in S_4 \)). In the notation there, the set of all such \( \langle x^0 x^1 x^2 \rangle \in \mathbb{P} S^3 \) is an algebraic set \( X \cap Y \) of dimension at least three.

Since \( Y \) is a very special subspace, one can hope it will not also give a very special intersection with \( X \). That is, an intersection that entirely falls within the special locus corresponding to linearly dependent \( x^0, x^1, x^2 \). The following simple result encourages this expectation.

**Proposition 4.1.** Let \( \dim S_1 = 3, f \in S_4 \). There exist distinct \( \langle x^0 \rangle, \langle x^1 \rangle, \langle l \rangle \in \mathbb{P} S^1 \) such that \( x^0 x^1 l = f = 0 \).

*Proof.* The case \( f = 0 \) being trivial, let us assume \( f \neq 0 \). Since the image of the (vector) Veronese map \( S^1 \to S^4, x \mapsto x^4 \), spans \( S^4 \), we can fix \( x^0 \in S^1 \) with

\[
x^0 x^1 l = f = 0.
\]

It follows, in particular, that \( g := x^0 x^1 l - f \neq 0 \). The dimension of \( V := \text{Ker} g_{2,1} \) is at least three because \( g_{2,1} \) maps \( S^2 \) into \( S^1 \). Since the locus \( X \subset \mathbb{P} S^2 \) given by reducible forms is a hypersurface, we have that the intersection \( Y := \mathbb{P} V \cap X \) is an algebraic set of dimension at least one. For distinct \( \langle x \rangle, \langle y \rangle \in \mathbb{P} S^1 \), we have that \( \langle x^2 \rangle, \langle y^2 \rangle \in Y \) implies \( \langle x^2 + y^2 \rangle \in Y \), and \( x^2 + y^2 \) is a simply degenerate quadratic form (char \( K = 0 \neq 2 \)). We deduce that the set \( U \) of \( \langle x^1 l \rangle \in Y \) with distinct \( \langle x^1 \rangle, \langle l \rangle \in \mathbb{P} S^1 \), is a nonempty open subset of \( Y \). But \( \langle x^1 l \rangle \in U \) means that \( x^1 l - g = 0 \), and \( x^1 l - f = x^0 x^1 l - f \). Hence it remains only to prove that we can choose \( \langle x^1 \rangle, \langle l \rangle \) different from \( \langle x_0 \rangle \).

Suppose then that all \( q \in U \), and hence all \( q \in Y \) are divisible by \( x_0 \). We can choose two distinct \( \langle y \rangle, \langle z \rangle \in \mathbb{P} S^1 \) such that \( \langle x^0 y \rangle, \langle x^0 z \rangle \in Y \). Let

\[
q \in V - \{ x^0 y, x^0 z \}.
\]

It can not be \( q = x^0 w \) with \( w \in S^1 \), otherwise \( y, z, w \) would be linearly independent, and hence \( x^0 \in \langle y, z, w \rangle \) (this would lead to \( x^0 \in V \), and henceforth \( x^0 x^1 l = f = 0 \), meanwhile \( x^0 x^1 l = f = 0 \)). If \( q \in Y \) we can find \( q' \in U - \{ x^0 y, x^0 z \} \), so that \( q' = x^1 l \) with \( \langle x^0 \rangle, \langle x^1 \rangle, \langle l \rangle \) all distinct as required.

We are left with the case when \( q \notin Y \), so that \( q \) is nondegenerate. Note that the (distinct) lines \( y = 0 \) and \( z = 0 \) in \( \mathbb{P} S_1 \) do not meet at a point lying on the line \( x^0 = 0 \), otherwise \( x^0 \in \langle y, z \rangle \) which would lead to \( x^0 x^1 l = f = 0 \) as before. Hence we can find \( w \in \langle y, z \rangle \) such that the line \( w = 0 \) meets \( q = 0 \) in distinct points that are...
also outside the line \( x^0 = 0 \). Now \( \mathbb{P}\{ q, x_0 w \} \subset \mathbb{P} V \) gives a pencil of conics in \( \mathbb{P} S_1 \). Looking at its base points, we easily deduce the existence of a simply degenerate form \( x^1 I \), with \( \{ x^1 \}, \{ I \} \) both different from \( \{ x_0 \} \) as required.

We tried to refine the above arguments to get linearly independent \( x^0, x^1, I \) with \( x^0 x^1 I = f = 0 \). But, in view of our goal, we found easier to adapt the proof of Proposition 3.1 to the special case when \( l \in \{ x^0, x^1 \} \) and \( \{ x^0 \}, \{ x^1 \}, \{ I \} \in \mathbb{P} S_1 \) all distinct. At the moment of writing, we do not know if linearly independent \( x^0, x^1, x^2 \in S^1 \) with \( x^0 x^1 x^2 = f = 0 \) can be found for every \( f \in S_4 \).

5. The special case

The following proposition is about the special case of linearly dependent \( x^0, x^1, I \) (but with \( \{ x^0 \}, \{ x^1 \}, \{ I \} \in \mathbb{P} S_1 \) all distinct, i.e., \( x^0, x^1, I \) are pairwise linearly independent). This can be proved much like Proposition 3.1, but at the cost of leaving out a (more) special case, which still needs work. That is why below we are adding the hypothesis that \( x^1 2 - f, x^2 2 - f \) and \( I^2 - f \) do not vanish. We shall show how to remove this hypothesis at the end of this section.

**Proposition 5.1.** Let \( \dim S_1 = 3, f \in S_4 \). If there exist linearly dependent, but pairwise linearly independent, \( x^0, x^1, I \in S^1 \), such that \( x^0 x^1 I = f = 0, \) but \( x^1 2 - f, x^2 2 - f \) and \( I^2 - f \) are all nonzero, then \( \text{rk } f \leq 7 \).

**Proof.** Let us choose \( y \in \{ x^0, x^1 \}^1 - \{ 0 \}, x_1 \in \{ x^0 \}^1 - \{ y \} \) with \( l - x_1 = 1, x_0 \in \{ x^1 \}^1 - \{ y \} \) with \( l - x_0 = 1 \) and set

\[
V_0 := S^4 \langle x_1, y \rangle, \quad V_1 := S^4 \langle x_0, y \rangle, \quad V_2 := S^4 \langle x_0 - x_1, y \rangle
\]

\((V_0, V_1, V_2 \subset S_4) \). Let

\[
\sigma : V_0 \oplus V_1 \oplus V_2 \rightarrow V_0 + V_1 + V_2
\]

be the canonical map \((v_0, v_1, v_2) \mapsto v_0 + v_1 + v_2 \). We have

\[
\text{Ker } \sigma = \langle w_0, w_1, v \rangle,
\]

with

\[
w_0 := \langle 0, x^2, -y^4 \rangle, \quad w_1 := \langle y^4, 0, -y^4 \rangle, \quad v := \langle x_1 y^3, -x_0 y^3, (x_0 - x_1) y^3 \rangle.
\]

From \( x^0 x^1 l - s = 0 \) follows that \( f \in V_0 + V_1 + V_2 \). Then \( W := \sigma^{-1}(\{ f \}) \) is a four-dimensional vector space. For each \( i \in \{ 0, 1, 2 \} \), let \( W_i \) be the image of \( W \) in the summand \( V_i \) through the projection map \( V_0 \oplus V_1 \oplus V_2 \rightarrow V_i \), and let us denote by \( \alpha_i \) the restriction \( W \rightarrow W_i \). For all \( w \in \sigma^{-1}(f) \) we have

\[
f = f_0 + f_1 + f_2, \quad f_i := \alpha_i(w) \in W_i \ \forall i.
\]

From \( \square \) it follows that

\[
x_1 y^3, y^4 \in W_0, \quad x_0 y^3, y^4 \in W_1, \quad (x_0 - x_1) y^3, y^4 \in W_2.
\]

Hence for every decomposition \( \square \) we have

\[
W_0 = \{ f_0, x_1 y^3, y^4 \}, \quad W_1 = \{ x_0 y^3, f_1, y^4 \}, \quad W_2 = \{ y^4, (x_0 - x_1) y^3, f_2 \}
\]

(therefore \( 2 \leq \dim W_i \leq 3 \) for each \( i \)).

\[\text{The notation } V_2 \text{ is slightly misleading, but it speeds up the exposition.}\]
If \( \dim W_i = 2 \) for some \( i \), we can choose \( w \) such that the decomposition (10) becomes
\[
    f = g(z, y) + h(t, y)
\]
with \( y, z, t \in S_i \) linearly independent, and the result follows from Proposition 2.5.

From now on, we can assume that \( \dim W_i = 3 \) for all \( i \). Then we can exploit Lemma 2.4 for each \( i \) and get varieties \( R_i, R_i' \) (with the obvious meaning of the notation). For each \( i \), let
\[
    \alpha_i : \mathbb{P}W - \mathbb{P}(w_0, w_1, v) \to \mathbb{P}W_i, \quad (w) \mapsto (\alpha_i(w))
\]
and set
\[
    \widehat{R}_i := \alpha_i^{-1}(R_i) \quad \text{and} \quad \widehat{R}_i' := \alpha_i^{-1}(R_i') .
\]

We are now in a situation similar to that of Proposition 2.3 and the loci \( \widehat{R}, \widehat{R}' \) are cylinders with vertices the (aligned, at infinity) points \( (w_0), (w_1), (w_0 - w_1) \). As in that situation, the analysis can be pursued in different ways, one of which we outline as follows.

The good news brought by Lemma 2.4 is that \( R_i' \) always consists of at most two points. Suppose first that for \( W_0 \) we fall in Case 1a of Lemma 2.4 with \( R_0 \) degenerate, so that there exists
\[
    (z) \in \mathbb{P}W_0 - \mathbb{P}(x_1 y^3, y^4)
\]
with \( \rk z = 1 \). Then we can choose \( w \in (\alpha_0^{-1}(z), w_0) - \{w_0\} \) such that \( \rk \alpha_1(w) \leq 3, \rk \alpha_2(w) \leq 3 \). Hence (10) for such a \( w \) gives \( \rk f \leq 1 + 3 + 3 = 7 \). The same argument works if for \( W_1 \) (or even for \( W_2 \)) we fall into Case 1a of Lemma 2.4 with \( R_1 \) (or, respectively, \( R_2 \)) degenerate. With these cases excluded, it is not difficult to check that if at most one among \( W_0, W_1, W_2 \), say \( W_i \), leads to Case 2 in Lemma 2.4, then we have \( (\widehat{R}_j \cap \widehat{R}_k) - (\widehat{R}_j' \cup \widehat{R}_k' \cup \widehat{R}_i') \neq \emptyset \), with \( j, k \) being the two indices other than \( i \).

This clearly gives \( \rk f \leq 7 \) (as in the proof of Proposition 3.1).

Now, we can assume that for \( W_0, W_1 \) we fall in Case 2 of Lemma 2.4, that is,
\[
    W_0 = \{x_1^2 y^2, x_1 y^3, y^4\}, \quad W_1 = \{x_0^2 y^2, x_0 y^3, y^4\} .
\]

Let us fix a decomposition (10) (corresponding to some \( w \)). Note that, by the choices of \( x_0, x_1, y \) at the beginning of the proof and by (8), we have \( x^0 \cdot f_0 = x^1 - f_1 = l - f_2 = x^0 \cdot y = x^1 \cdot y = l \cdot y = 0 \). From (1) easily follows that
\[
    x^0 l - f = \alpha y^2, \quad x^1 l - f = \beta y^2 ,
\]
for some \( \alpha, \beta \in K \). Hence \( (\beta x^0 - \alpha x^1) \cdot l - f = 0 \). Since \( l^2 - f \neq 0 \), \( (\beta x^0 - \alpha x^1) \) and \( l \) are linearly independent, so that \( \rk f \leq 7 \) follows from Proposition 2.5.

Basically, the analysis in the above proof stopped when facing a very special \( f \) (such that two among \( W_0, W_1, W_2 \) fall in Case 2 and after reordering \( x^0, x^1, l \) accordingly, we have that \( \beta x^0 - \alpha x^1 \) is proportional to \( l \)). In order to settle this and then reach our goal of giving a new proof that \( \rk f \leq 7 \), we now (more generally) work out the condition \( l^2 - f = 0 \). This way, the result will again be included, as Proposition 2.5 in [7, Theorem 3.6], but in this case we propose a proof which looks different (and fits into the approach of the present work).

**Proposition 5.2.** Let \( \dim S_i = 3, f \in S_1 \). If there exist a nonzero \( l \in S_1 \) such that \( l^2 - f = 0 \) then \( \rk f \leq 7 \).
Proof. The dimension of $V := \text{Ker } f_{3,1}$ is at least 7, because $f_{3,1}$ maps $S^3$ into $S_1$. Let $W := V \cap lS^2$, so that $\dim W \leq 6$. If $\dim W = 6$ then $l - f = 0$ and therefore $f \in S^1(l)^4$, so that $rk f \leq 4$. If $\dim W = 5$ then $g := l - f$ is of rank one because its polarization $g_{2,1}$ is of rank one. This means that $g = z^3$ for some $z \in S_1$, and $l - z^3 = l^2 - f = 0$. If we take $y \in S_1$ such that $l - y = 1$, we have $f = yz^3 + h$ with $h \in S^1(l)^4$. Therefore, for whatever nonzero $m \in \{y, z\}^4$ we have $lm - f = 0$ and $l, m$ are linearly independent because $l - y = 1$, $m - y = 0$. Hence the result follows from Proposition 2.5.

From the above, now we can assume that $\dim W \leq 4$. Also recall that $\dim V \geq 7$. Therefore the image of $V$ under the projection map $\pi : S^* \rightarrow S^*/(l)$ (with $(l)$ being the ideal generated by $l$) is of dimension at least three. It easily follows that there exists $p \in V$ such that the cubic $p = 0$ in $\mathbb{P}S_1$ intersect the line $l = 0$ in three distinct points $P_0, P_1, P_2$. To be concise, we now use a bit of elementary scheme-theoretical language. The scheme-theoretic intersection $Z$ of $p = 0$ with the double line $l^2 = 0$ consists of $P_0, P_1, P_2$ doubled inside three lines $x^0 = 0, x^1 = 0, x^2 = 0$ (a point $P$ doubled inside a line $l$ is the degree two zero-dimensional scheme with ideal sheaf $I^2_P + I_l$). It is easy to see that the ideal of $Z$ in $S^*$ is generated by $p, l^2$, so that $x^0 x^1 x^2 = \alpha p + xl^2$, with $\alpha \in K, x \in S^1$. It follows that $x^0 x^1 x^2 - f = 0$, and $\{x^0\}, \{x^1\}, \{x^2\}$ are distinct because the lines $x^i = 0$ meet $l = 0$ in distinct points. Therefore, in view of Proposition 3.1 and Proposition 5.1, we can assume that for some $i$ we have $x^i - f = 0$. But $\{x^i\} \neq \{l\}$, because the lines $x^i = 0$ and $l = 0$ meet only at $P_i$. Hence $l + x^i$ and $l - x^i$ are linearly independent,

$$(l - x^i) (l + x^i) - f = (l^2 - x^2) - f = 0,$$

and the result follows from Proposition 2.5. \qed

Propositions 4.1 [6] and 5.1 [7] together give a bound of seven for every plane quartic. Since it is well known that a nondegenerate conic together with a doubled tangent line gives a rank seven plane quartic, we end up with Kleppe’s result that the maximal rank for plane quartics is seven (which solves the polynomial little Waring problem for $n = 3, d = 4$).
